

or

$$g = \frac{4\pi G}{r^2} \int_0^r r'^2 \rho(r') dr' \quad ; \quad (2-57)$$

now we may, without danger of confusion, write  $r$  instead of  $r'$  in the integrand, a convenient and customary though somewhat questionable simplification since, after the integral sign,  $r$  denotes the integration variable, whereas as the upper limit of integration and before the integral sign,  $r$  denotes the radius vector of  $P$  at which  $V$  and  $g$  are considered (Fig. 2.2).

The physical interpretation of (2-57) is very clear. The part of the earth's mass which is enclosed by the surface  $S_P$  is

$$M_P = \int_{r'=0}^r \iint_{\sigma} \rho(r') r'^2 dr' d\sigma = 4\pi \int_0^r \rho r^2 dr \quad (2-58)$$

by (2-52), so that (2-57) may be written

$$g = \frac{GM_P}{r^2} \quad , \quad (2-59)$$

in agreement with (2-33) and (2-37). This is the attraction of the "core" within  $S_P$ , whereas the attraction of the outer shell is zero, by (2-36). This is quite analogous to the homogeneous case (2-37).

Using this analogy, it is also extremely convenient and useful to introduce the *mean density*  $D$  within the sphere  $S_P$  by

$$D = \frac{3}{4\pi r^3} M_P \quad , \quad (2-60)$$

in agreement with (2-38), which is the fictitious constant density producing the same attraction (2-59) on and outside  $S_P$  as the real density distribution  $\rho(r)$  inside  $S_P$ . By (2-58) we have

$$D = \frac{3}{r^3} \int_0^r \rho r'^2 dr' = D(r) \quad (2-61)$$

( $D$  is constant within  $S_P$  but, depending on  $S_P$ , it depends on  $r$ !). Finally, (2-58), (2-59), and (2-61) give

$$g(r) = \frac{4\pi G}{3} r D(r) \quad ; \quad (2-62)$$

a useful formula which is the analogue of (2-39) for a heterogeneous, spherically symmetric stratification.

### 2.3 Homogeneous Ellipsoid: First-Order Theory

Since the earth is not homogeneous, the theory of a homogeneous ellipsoid only plays an auxiliary and preparatory role, although an important one.

Consider a homogeneous ellipsoid of revolution, of density

$$\rho = \text{const.} \quad (2-63)$$

By first-order theory we mean, as usual, that only terms linear in  $f$  are considered,  $O(f^2)$  being neglected. To this approximation, its surface is given by (2-6),

$$r = R \left[ 1 - \frac{2}{3} f P_2(\cos \theta) \right] . \quad (2-64)$$

This equation may be interpreted geometrically as in Fig. 2.3: the ellipsoid consists of

FIGURE 2.3: Ellipsoid and mean sphere

a "basic sphere" of radius  $R$  and "extra material" (plus or minus). Thus its potential is given by

$$V = V_{\text{sphere}} + v . \quad (2-65)$$

Here  $v$  denotes the potential due to the "extra material", which to our approximation may be considered compressed into a surface layer on the sphere, of surface density

$$\mu = \rho h , \quad (2-66)$$

where  $\rho$  is the volume density and  $h$  the thickness of the layer (Fig. 2.3). The potential of this layer is given by (1-5):

$$v = G \iint_S \frac{\mu}{l} dS = G\rho \iint_S \frac{h}{l} dS , \quad (2-67)$$

in view of (2-63). Putting

$$dS = R^2 d\sigma , \quad (2-68)$$

we may replace the integration over the sphere  $S$  by an integration over the unit sphere  $\sigma$ :

$$v = G\rho R^2 \iint_{\sigma} \frac{h}{l} d\sigma \quad (2-69)$$

The deviation  $h$  of the ellipsoid from the sphere (Fig. 2.3) is, by (2-64),

$$h = -\frac{2}{3} f R P_2(\cos \theta) \quad , \quad (2-70)$$

so that (2-69) becomes, with  $\theta'$  as integration variable,

$$v = -\frac{2}{3} G\rho f R^3 \iint_{\sigma} \frac{P_2(\cos \theta')}{l} d\sigma \quad (2-71)$$

Assuming the potential to be calculated at a point with  $r > R$  (external potential), we may apply (1-53) with  $r' = R$  (remember that we have a surface layer on the sphere  $r = R$ ), so that

$$\frac{1}{l} = \sum_{n=0}^{\infty} \frac{R^n}{r^{n+1}} P_n(\cos \psi) \quad (2-72)$$

This is substituted into (2-71) and the order of integral and sum is interchanged, obtaining with  $v = v_e$  (external potential):

$$v_e = -\frac{2}{3} G\rho f R^3 \sum_{n=0}^{\infty} \frac{R^n}{r^{n+1}} \iint_{\sigma} P_2(\cos \theta') P_n(\cos \psi) d\sigma \quad (2-73)$$

Now by (1-51) with  $Y_k(\theta', \lambda') = P_2(\cos \theta')$ , orthogonality removes all terms except the one with  $n = 2$ , for which by (1-49) we simply get

$$\iint_{\sigma} P_2(\cos \theta') P_2(\cos \psi) d\sigma = \frac{4\pi}{5} P_2(\cos \theta) \quad (2-74)$$

Thus (2-73) reduces to

$$v_e = -\frac{8\pi}{15} G\rho f \frac{R^5}{r^3} P_2(\cos \theta) \quad (2-75)$$

This is added to the potential of a homogeneous sphere as given by (2-31) with

$$M = \frac{4\pi}{3} \rho R^3$$

by (2-38), in agreement with (2-65). The result is

$$V_e = \frac{4\pi}{3} G\rho \left[ \frac{R^3}{r} - \frac{2}{5} \frac{R^5}{r^3} f P_2(\cos \theta) \right] \quad (2-76)$$

This is the desired formula for the external potential of a homogeneous ellipsoid.

For the internal potential ( $r < R$ ) we proceed in exactly the same way, substituting

$$\frac{1}{l} = \sum_{n=0}^{\infty} \frac{r^n}{R^{n+1}} P_n(\cos \psi) \quad , \quad (2-77)$$

instead of (2-72), into (2-71) and obtaining the internal potential  $v = v_i$ . Again, orthogonality eliminates all terms except  $n = 2$ , and (2-74) again applies. The result is

$$v_i = -\frac{8\pi}{15} G\rho f r^2 P_2(\cos \theta) \quad . \quad (2-78)$$

In order to apply (2-65), we must use for the inner spherical potential the expression (2-43), obtaining

$$V_i = \frac{4\pi}{3} G\rho \left[ \frac{3}{2} R^2 - \frac{1}{2} r^2 - \frac{2}{5} f r^2 P_2(\cos \theta) \right] \quad (2-79)$$

as the formula for the internal potential of a homogeneous ellipsoid. In both formulas (2-76) and (2-79), terms of  $O(f^2)$  are neglected. These two formulas will serve as a basis for computing the potential of a heterogeneous (stratified) ellipsoid.

## 2.4 Heterogeneous Ellipsoid

*Homogeneous shell.* As a preparation, consider a thin ellipsoidal shell (of infinitesimal thickness), bounded by two ellipsoids  $E_1$  and  $E_2$ , within which the density  $\rho$  is constant.

In the same way as we have assigned, in Fig. 2.3, to an ellipsoid  $E$  its mean sphere  $S$  (of radius  $R$ , which defines  $R$  as mean radius for  $E$ ), we can assign such spheres to  $E_1$  and  $E_2$ ; let  $q$  be the mean radius of the inner ellipsoid  $E_1$  and  $q + dq$  the mean radius of the outer ellipsoid  $E_2$  (remember they are infinitesimally close to each other). Similarly let  $f$  denote the flattening of  $E_1$  and  $f + df$  that of  $E_2$ , and let  $f$  be a function of  $q$ ,

$$f = f(q) \quad , \quad (2-80)$$

so that

$$df = \frac{df}{dq} dq \quad . \quad (2-81)$$

Then the equation of  $E_1$  is, by (2-64),

$$r = q \left[ 1 - \frac{2}{3} f P_2(\cos \theta) \right] \quad (2-82)$$

and that of  $E_2$ ,

$$r = (q + dq) \left[ 1 - \frac{2}{3} (f + df) P_2(\cos \theta) \right] \quad , \quad (2-83)$$

keeping in mind that  $f$  and  $df$  depend on  $q$  through (2-80) and (2-81).

Now comes the important step. In order to determine the potential of the shell, consider the homogeneous solid ellipsoid bounded by  $E_2$ , of constant density  $\rho$ , and
